ABSTRACT

This is the teacher's guide to accompany the student guide which together comprise one of five computer-oriented environmental/energy education units. The computer program, ENERGY, at the base of this unit, simulates the pattern of energy consumption in the United States. The total energy demand is determined by energy use in the various sectors such as the industrial sector, the transportation sector, the utilities sector, and so on. The demand for energy is shown to grow exponentially in each sector. Students are asked to balance supply of energy with demand by adjusting factors in each sector. This teacher's guide presents: (1) suggestions on introducing the unit; (2) student guide exercises and answers; (3) follow-up activities; and (4) an annotated source list. This unit is appropriate for social studies and environmental education courses grades 9 through 14. (MR)

INTRODUCTION TO THE UNIT

Unit Description

Subject Areas: Social Studies, Environmental Education

Topic: The U.S. Energy Crisis

Abstract: This unit is organized around an operating model which simulates important systemic aspects of the energy crisis in the United States. Working with this simulation, students will confront such questions as: "How can pollution be reduced without increasing the demand for energy?" and "If most of the population used mass transit instead of private cars, how much energy would be saved and how would this affect the quality of life?"

The computer program, ENERGY, at the base of the unit simulates the pattern of energy consumption in the United States. The total energy demand is determined by energy use in various sectors such as the industrial sector, the transportation sector, the utilities sector, and so on. The demand for energy is shown to grow exponentially in each of these sectors. The students' task will be to balance the supply of energy with the current demand by adjusting factors in each sector. Some of the adjustable factors are industry's production level, pollution standards and the availability of mass transit systems. In making these adjustments to reduce the demand for energy, students will be faced with the consequences of making these changes, as reflected in indices such as pollution level, economic well-being, general satisfaction level and so forth.

The ENERGY model is designed for use both as the basis for a role-playing game in which students represent different elements of society attempting to agree on solutions to the energy problem and as an experimental device for students to test various strategies and solutions.

Grade Level: 9-14

Computer Language: BASIC

Program Name: ENERGY

Objectives

The primary objectives of this unit are:

1. To provide an operational model of the energy system in the United States as a vehicle for the study of the energy problem.

2. To foster a better understanding of the energy crisis. Specifically, this understanding relates to:

    a. The causes of the energy crisis

    b. The nature of the growth of the energy shortage

    c. The pattern of energy use in the United States

    d. The relationship between the supply of energy and energy consumption

    e. The nature of the trade-offs that must be considered when changing the pattern of energy consumption

3. To provide students with a basic understanding of the complexity of the energy crisis. Reaching this objective will involve the students in comparing the model with their view of the problem.

Reasons for Studying the ENERGY Unit

In this age of crisis upon crisis, it is imperative that students be given an opportunity to confront and cope with real world problems. They need to engage in decision making and problem solving activities and exercises that involve setting priorities for energy use, acceptable sources of energy, the quality of the environment, economic changes and acceptable life styles. They need to develop the skills and insights necessary to understand the structure, functioning and impact of the various systems and subsystems that interact in complex ways to create a particular problem or crisis. Senator Howard H. Baker of Tennessee, a strong supporter of environmental education, states the need in the following way:

> Since the present problems result largely from ignorance and indifference, corrective action must alleviate these conditions. We cannot expect improvement unless public attitudes change, unless a better appreciation of environmental processes is inculcated in the present and future generations. Our great need today is a knowledgeable citizenry, conscious of their surroundings and willing to

> take the necessary social, economic and political steps to assure a better environment for all. The cost is great; but the benefits are still greater and the consequences of not acting will be profoundly tragic for ourselves and future generations.[1]

The Citizens Advisory Council on Environmental Quality in a recent report to the President pointed specifically to our education system charging that "our formal education system has done little to produce an informed citizenry sensitive to environmental problems, prepared and motivated to work toward their solution."[2]

Within recent years a renewed emphasis has been placed on environmental ecological education.[3] Educational materials for teachers and students concerning the concept of energy and its relationship to man and his environment, however, remain scarce.[4] Frank B. Brouillet, Superintendent of Public Instruction for the State of Washington, summarizes the need for energy related curriculum materials this way:

> As educators work to foster a greater understanding of society's environmental problems, we can best succeed by teaching the ecological relationships and principles that underlie problems such as Energy. We need to help students learn of Energy's relationship to man's environment, and learn to make decisions about possible alternative approaches and solutions to Energy problems.
>
> The Energy concerns of our society demand that the generation of students now in our schools become environmentally literate to the degree that they understand the environmental implications of human activities viewed from the perspective of social needs and values as they relate to general public policy.[5]

The "U.S. Energy Crisis" curricular unit on energy provides a realistic framework for the study of the problems involved in the energy crisis today. Using a computer simulation, students have the opportunity to experiment with many energy-use patterns and different pollution standards and to see the effects not only on energy resources but on economic conditions and general public satisfaction.

Exercises of all types may be designed around the ENERGY simulation, allowing students to become actively involved in trying to solve the energy crisis and confronting the effects of different measures. Students may also analyze the mathematical model underlying ENERGY, thereby deepening their understanding of the interrelationships among energy issues and of the limits of the mathematical relationships used in this model.

Description of the ENERGY Program and Model

The ENERGY program simulates the effects of changes in 10 energy-use factors on overall energy supply and demand as well as on pollution levels, economic well-being, and general satisfaction. The factors which students may change are

Industry	1. Production Level
	2. Pollution Standards
Utilities	3. Production Level
	4. Pollution Standards
Transportation	5. Pollution Standards
	6. Mass Transportation
	7. Automobile Efficiency
Home	8. Appliances
	9. Home Heating and Lighting
Business and Schools	10. Heating and Lighting

Changes are entered as simple percentage increases or decreases in any or all factors each year, beginning with given conditions in 1975. Results are either listed or graphed for each year, with graphs showing the total supply and demand results for every year between 1975 and selected future years. Runs may be made for as many years as the user wishes.

The challenge of this program is for the user to introduce changes in order to keep demand for energy within the available energy supply and to reduce pollution while increasing economic well-being and general public satisfaction. For each factor not changed by the user each year, the program calculates

an automatic change, reflecting the trend of growing consumption. In addition, unexpected events are randomly introduced which increase the otherwise nonrenewable energy supply.

Directions for running ENERGY and a sample run are given in the Student Guide, pages 10-13.

The ENERGY model is limited to simulating effects on pollution, economic and satisfaction levels of changes in pollution standards and patterns of use of energy resources, assumed to be nonrenewable. It assumes that energy consumption is growing exponentially and that two things may extend the available supply of energy--changes in patterns of consumption and new energy sources being found. The model also assumes that changes in consumption patterns will directly influence the economic well-being of the nation and the general satisfaction of the people.

Basically, the relationships used by the ENERGY model are

INCREASES IN INDEPENDENT VARIABLES	RESULTING EFFECTS ON DEPENDENT VARIABLES				
	Energy Demand (ED)	Energy Resources (ES)	Pollution Level (PL)	Economic Well-Being (EWB)	General Satisfaction (GSL)
1. Industrial Production Level (IPL)	Inc.	Dec.	Inc.	Inc.	Inc.
2. Industrial Pollution Standards (IPS)	Inc.	Dec.	Dec.		
3. Utilities Production Level (UPL)	Inc.	Dec.	Inc.	Inc.	
4. Utilities Pollution Standards (UPS)	Inc.	Dec.	Dec.		
5. Transportation Pollution Standards (TPS)	Inc.	Dec.	Dec.		
6. Mass Transportation (TMT)	Dec.	Dec.			
7. Automobile Efficiency (TE)	Dec.	Dec.			
8. Appliances (A)	Inc.	Dec.			Inc.
9. Home Heating and Lighting (HH)	Inc.	Dec.			Inc.
10. Schools and Business, Heating and Lighting (BSH)	Inc.	Dec.			Inc.

* Energy resources will constantly decrease unless all energy demand ceases. The only variable which can increase the resources is an "unexpected event" which is randomly introduced by the program itself.

The mathematical relationships are described on pages 17-19 of the Student Guide.

The data for the ENERGY simulation were drawn, for the most part, from the following three publications:

1. Hirst, Eric and John C. Moyers, "Efficiency of Energy Use in the United States," in Science, Vol. 179, March 30, 1973, pp. 1299-1304.

2. Patterns of Energy Consumption in the United States, prepared by Stanford Research Institute for the Office of Science and Technology. Washington: Government Printing Office, 1972.

3. A Time To Choose America's Energy Future. Final Report of the Energy Policy Project of the Ford Foundation. Cambridge, Mass.: Ballinger Publishing, 1974.

INTRODUCING STUDENTS TO THE SUBJECT AND UNIT

Introducing the Subject of the U.S. Energy Crisis

1. Students should read the background information on pages 1-7 of the Student Guide.

2. An excellent overview of the topic is provided in the 11-page article "Energy and the Environment," by John M. Fowler, in the December, 1972 issue of The Science Teacher.

3. Some of the activities suggested in the following sources will serve as good introductory activities:

   a. Energy and Man's Environment: Elementary through Secondary Interdisciplinary Activity Guide, available from Energy and Man's Environment, 2121 Fifth Avenue, Seattle, Washington 98121.

   b. "The Energy Question: Problems and Alternatives" in Intercom, No. 73, Teaching Toward Global Perspectives, available from Intercom, 218 East 18th Street, New York, New York 10003.

Preparing Students to Use the ENERGY Simulation.

1. Students should have a clear understanding of the limits of the ENERGY model before proceeding to use the simulation. The model's scope and the assumption on which it is based are described on pages 14-20 of the Student Guide. Students will discern additional assumptions as they work with the simulation and study the model.

   All students will need to understand the elementary relationships, between the energy-use factors and supply, demand, pollution, economic well-being and general satisfaction. The table on page 17 of the Student Guide identifies the general relationships in simple terms. The equations which determine the actual relationships used in the model are given on pages 17-19 of the Student Guide.

2. The model makes use of randomly introduced "news flashes" which announce the availability of new sources of energy and hence increase the otherwise nonrenewable energy resources. Students should understand that these events are included to simulate real-life possibilities which bear on energy availability.

3. Students should understand the procedures for running the ENERGY program, as outlined on pages 10-13 of the Student Guide.

STUDENT GUIDE EXERCISES: SUGGESTIONS AND ANSWERS

Suggestions

Exercise 1. All three parts of this exercise are sufficiently easy that all students may be expected to complete them. Scheduling of terminal time (about 10 minutes for each run) will require care to insure that all students can complete the exercise. In cases where time is limited, or other difficulties exist, parts (b) and (c) can be made optional for interested or advanced students. You may want students to submit their analyses of each run in a short written report. Comparisons of runs and student comments should be material for lively class discussion.

Exercise 2. The set of questions in this exercise will serve as a good overview of the ENERGY model's limitations. Class discussion of answers may be referred back to pages 10-20 of the Student Guide. This set of questions forms the basis of Follow-Up Activities, which are discussed in the next section of the Teacher's Guide.

Exercises 3. & 4. Average to advanced students may enjoy tackling this energy problem from these special angles. These exercises may be done individually or by committees of three to four students, who might compete for "election" on the basis of their 1975-1980 records and their new proposals.

Answers to Exercises

1. Runs and analyses will vary. Student grasp of the principle relationships in the ENERGY model should be reflected in improved strategies for runs (b) and (c).

2. a. 10

   b. No changes by student can increase energy supply, due to the models use of specifically nonrenewable energy sources (see pages 17 and 19 of the Student Guide).

   c. Answers will depend on strategies used and incidences of news flashes.

   d. "News flash" events increase energy supply by 2-10% (see page 20 of the Student Guide).

e. No. As the table on page 17 of the Student Guide shows, changes in factors 8, 9 and 10 do not cause changes in economic well-being. Some runs, however, may obscure this fact; hence, students should be referred to the Student Guide for clarification.

f. See again the table on page 17. Factors 1, 8, 9 and 10 alone effect general satisfaction, though runs may not show this effect clearly.

g. No consistent relationship between pollution level and general satisfaction has been included in the simulation. (See table, page 17.)

3. & 4. Runs will vary as will "Reports to the People."

FOLLOW-UP ACTIVITIES

I. The Limits and Scope of the ENERGY Model

1. On the basis of students experience with the ENERGY program and their answers to Exercise 2, the limits and biases of the ENERGY model may be discussed profitably by the class.

    a. As a preparation for class discussion, students may be asked to look over their answers to Exercise 2 and to note for each part how "realistic" they think the ENERGY model is.

    b. Suggestions may be gathered for changing the mathematical relationships in the model to be more realistic and advanced students with programming skills may be assigned the job of writing a revised program of their own. Further exercises could then be done with the student-written programs.

2. Special assignments can be made for researching independent variables excluded from the ENERGY model (such as population growth) and working out their effects within the ENERGY model. Advanced students may wish to create a new version of the program adding new variables.

II. Research Into Energy Sources and Issues

Any of the following will be interesting topics for students to research in order to broaden their understanding of the present crisis concerning energy resources, uses, and other issues. Brief class presentations can provide a focus for research and a way to maximize the exposure to information.

1. Present status and future prospects for new energy sources such as new fossil fuel deposits, geothermic energy and solar energy.

2. Current status of natural gas, oil, and coal resources and estimated future levels.

3. Energy use in any of the five societal areas in terms of consumption, waste, pollution and other factors.

4. Energy production and consumption in Western nations compared to that in Asian, South American or African nations.

5. The politics of oil.

6. Local ecological concerns related to energy production and consumption, such as land degradation or air pollution.

7. How pollution control devices work.

III. Research Into Ways and Means

An eye-opening experience for students will be to research the stages which measures for improving the energy situation must go through before measures can be implemented. Some specific areas for investigation might be:

1. Setting industrial pollution standards.

2. Setting automobile pollution control standards.

3. Establishing "energy-use" labelling laws for appliance manufacturers.

4. Establishing building standards to reduce energy waste.

5. Establishing legislation for or against nuclear power sources.
